

What Proxy Is, and How the Whole Thing Works

The complete system in plain language — what the product does, the pieces it's made of, and how one meeting flows through all of them. Read this first; each deep-dive (01–06) is a zoom into one piece named here.

Proxy is an AI that joins your company's meetings already knowing your company's software — and can check what's being said against what's actually true, before it speaks. When asked, it does things (runs a test, pulls a number, drafts a plan) and proves the result. Unprompted, it speaks up like the best-informed person in the room. Everything it states is backed by a real source, or it stays quiet. Anything it changes in a real system is a draft a human approves.

THE CORE PROMISE

Every other meeting AI can only summarize what was **said**. Proxy is the only participant that can compare what's said to what's **true** in the company's own systems — because it did the homework before the meeting, and it has hands to check things during it.

The three things Proxy remembers

The whole system is a set of AI agents working over three shared memories. Understand the memories and everything else follows.

- **The Estate Graph** — a verified map of the company's software: every system, how it works, who owns it, what it connects to. Built before any meeting. This is its *long-term memory* — what the company *is*. (Deep-dive 01.)
- **The Meeting Page** — a live, structured summary of the meeting happening right now: the claims made, the decision forming, what's unresolved. This is its *working memory* — what's happening *now*. (Deep-dive 02.)
- **The Ledger** — a running record of everything Proxy thought, did, proved, and chose not to say. This is its *notebook*, and its audit trail. (Deep-dives 04, 05.)

The agents (the workers)

- **The Scribe** — one agent whose only job is to keep the Meeting Page accurate, second by second, as people talk.
- **The unit experts** — one AI per piece of the company's software, each trained until it's an authority on its piece. When a meeting mentions `checkout`, the checkout expert quietly joins.
- **The Participant** — the one "mind" in the room that decides what's worth contributing. It has a fast side that constantly drafts ideas and a deep side that does real work to make an idea solid.
- **The Workshop worker** — the "hands." When something needs to actually be done (run code, build a model, draft a ticket), this agent does it in a safe sandbox and proves the result.

THE DESIGN RULE UNDERNEATH EVERYTHING

The agents don't call each other through a fixed script. They **react to shared memory**: the Scribe writes something on the Meeting Page, and whoever cares about that reacts. This is why the product is easy to extend — add a new expert or a new tool and the behavior grows, with no rewiring. The only things hard-coded are the safety floors (never state something unverified) and the data formats. Every actual judgment is made by an agent.

How one meeting flows through the whole system

Here is the entire product in one trace. Every deep-dive expands one moment of this.

One meeting, end to end. The loop: the conversation feeds the map, the map staffs the experts, the experts serve the conversation — and it never stops turning.

The parts of this spec

Each deep-dive is a standalone document that zooms into one piece of the trace above.

- **01 · Pre-meeting** — how we learn the company's software and build the Estate Graph.
- **02 · Meeting understanding** — how the Scribe builds the live Meeting Page from speech and screen.
- **03 · Reactive** — how Proxy handles anything it's asked: do it, help me do it, explain it, advise.
- **04 · Proactive** — how the Participant decides to speak up on its own, and does real work to earn it.
- **05 · Actions** — the "hands": one system that can do any task and prove it, for every use case.
- **06 · Experience** — how Proxy looks, feels, and shows up inside the meeting.

What it runs on

Plain, proven infrastructure: one **Postgres** database holds all three memories; the **Claude Agent SDK** runs every agent; a safe sandbox called **E2B** is where work gets done; standard **MCP** connectors reach into real systems; and two gateways (**LiteLLM** for cost metering, **Langfuse** for tracing) watch everything. The whole meeting runs for roughly a dollar to a dollar-fifty an hour, and gets cheaper and more accurate the longer it runs, because it learns from its own logs.
